

**MEDIUM VOLTAGE
OIL AND CAST RESIN
DISTRIBUTION TRANSFORMERS**

A product guaranteed by

Product range

Oil filled distribution transformers

Nominal ratings	from 25 to 2000 kVA
H.V. reference	7,2 - 12 - 17.5 - 24 kV
H.V. tapings off load	± 2.5% / ± 5%
Connections	Dyn11 - Yyn0
Cycles	50-50 / 60-60
Guarantee	24 months

Cast resin distribution transformers

Nominal ratings	from 100 to 2500 kVA
H.V. reference	7,2 - 12 - 17.5 - 24 kV
H.V. tapings off load	± 2.5% / ± 5%
Connections	Dyn11 - Yyn0
Cycles	50-50 / 60-60
Guarantee	24 months

Three phases oil and cast resin transformers, are manufactured and tested according to the IEC 60076-1 specifications.

Three phases oil transformers until 24 kV are in accordance with the EN 50588-1 and IEC Standards standards.

Cast resin transformers until 24 kV are in accordance with the EN 50451-1 and IEC 60076-1 standards.

Transformers can be manufactured in accordance with the VDE/DIN 0532, GOST, BS, NF, NEN particular specifications.

Manufacturing process of the oil distribution transformers

The cores (for oil and cast resin transformers)

The cores are constructed using thin sheets of cold rolled grain-oriented magnetic steel silicon insulated on both sides.

Conventional grain oriented steel (CGO steel) is used for transformers with normal no-load losses, while transformers with reduced no-load losses are built using higher quality HiB steel.

The core sheets are cut at an angle of 45°, thus allowing maximum magnetic flux in the rolling direction.

Then the sheets are stacked in layers of either single or multiple overlaps. The multiple overlap or “step-lap” method offers additional benefits in terms of lowering no-load losses and noise levels. Once the sheets are stacked, the core is compressed and glued to form a firmly bonded whole.

The majority of oil filled transformers have an oval-shaped core section having traditional stepped and fully filled round shape with a square mid section combined.

This method combines the benefits of a rectangular core section (simplicity of production) with those of a round core section (excellent short circuit withstand capability of the windings).

A product guaranteed by

The windings

High voltage windings

The high voltage windings are almost exclusively of layered construction.

The copper conductors are made of one or more round or square wires, completely insulated by pure cellulose paper or by double enamel.

The insulation between the layers consists of pre-coated kraft paper, applied in sheet form.

Low voltage windings

The low voltage windings are usually made of copper or aluminium (from 400 kVA) sheet conductor (foil); this reduces the axial stresses produced by short circuit to a minimum.

The maximum voltage between each turn is only a few volts. This allows the insulation needed between the turns (foils) to be limited to one thermo-hardening epoxy adhesive which cures and bonds during the drying process.

A product guaranteed by

The tank

The vast majority of distribution transformer tanks are constructed with cooling fins

In hermetically sealed transformers, the cooling fin design also can withstand the working pressure or the pressures required during the treatment and filling of the transformers.

This allows the tank to be totally filled (and hermetically sealed), thus guaranteeing a long life of the transformer and reducing maintenance.

For the oil type power transformers from 4 MVA, the tanks are normally fitted with corrugated panels and equipped with a conservator.

This cylindrical conservator acts as an expansion tank for the oil when it expands as the windings heat up. The oil conservator is often fitted with a gauge glass, an air vent, an air dryer and a protection relay.

After welding, the tank is shot-blasted to remove any scale, oil or other surface impurities, leaving a clean prepared surface for maximum adhesion of the paint coating. Air-drying paint is then applied by spraying or flooding.

Several coats of paint are applied, to a total thickness of at least 100 microns, thus guaranteeing adequate protection against corrosion for indoor or outdoor transformers.

The tanks may be galvanised upon request.

The active parts

The windings are pushed over the core legs and wedged up to fill the spaces between the core and winding as much as possible.

Interleaving the laminations of the upper yoke with the laminations of the core legs completes the magnetic circuit.

The porcelain or the plug-in bushings are mounted on the cover, which are then fixed onto the assembled active part.

The next step consists of connecting the windings to the bushings.

The transformers are fitted with an off load tap changer. This switch allows the increase or decrease of a certain number of turns while the transformer is disconnected from the electric system.

The voltage ratio of the active part is then tested, and the assembly is dried in a forced air oven to remove the moisture from the insulating materials. Once the active part has been dried in the forced-air oven, it is given a final comprehensive quality inspection and placed into the tank.

The top cover is then bolted onto the tank. The transformers are placed in a vacuum chamber and filled with pre-treated oil (filtered, dried and degassed) under deep vacuum. This ensures optimum impregnation of the insulation materials by the oil, giving the insulation structure maximum dielectrical strength.

The transformers are filled with a high quality mineral oil, which fully complies with the requirements of IEC standard 296

A product guaranteed by

Fittings and accessories

- Over-pressure valve applied above the cover of the tank
- Lifting hooks to draw out the inside part and the tank
- Base support with translation wheels and hooks to drag the transformer
- Rating plate
- Drain oil valve
- Thermometer pocket

Options

- Dial thermometer with two electrical contacts
- Protective block for hermetic transformers (DMCR or pressostat)
- MV voltage resin terminals to connect plug-in terminals
- Low voltage protecting terminals with protecting hoods
- And other on request

A product guaranteed by

Manufacturing process of the cast resin transformers

The windings

High voltage windings

The high voltage windings are made out of aluminum or copper strips and are designed to avoid that thermal expansion causes slips between conductors and resin.

The method of manufacture guarantees a perfect distribution of the electrical field and the absence of partial discharges as well as an excellent resistance to impulse stress.

Guarantees have also been given that the windings resist the external dynamic effects of short-circuits.

The dielectric materials used (resin, conductors, and insulators) are of class F.

The transformer has a working temperature rise limit of 100°K (Class F).

Low voltage windings

The low voltage windings are obtained from aluminum or copper strips with the same height of the primary limb to reduce to a minimum the axial strain due to short circuit currents. A class F insulating block insulates the coils.

Before mounting, the LV windings are immersed in alkyd resin and then polymerized at 150°C. This process guarantees excellent resistance to external agents (humidity and pollution of the atmosphere).

The winding is designed and made out so that the maximum working temperature rise at full load is equal to class F ($\Delta T=100^{\circ}K$).

The concentric shapes of the two windings (HV and LV) are maintained by special spacers - a support which allows the supply of the flux to be uniformly distributed and avoids the onset of abnormal vibrations.

The resin used in the casting system is an epoxy resin charged with very fine quartz powder, given the transformer the necessary characteristics to pass every test successfully.

The computerized monitoring ensures the accurate control of all phases of the process, from the preparation of the resin to the temperature control in the polymerization.

The epoxy resin used is of the class F thermal stability and the product is manufactured in conformity with the temperature limits given by the IEC 726 standards.

Fittings and accessories

Standard Fittings

- Lifting hooks
- Base structure with translation Wheels.
- H.V. Terminals
- L.V. Terminals
- Rating plate
- Ground plate
- 6 PTC sensors with an electronic converter.

Optional fittings

- PT 100 thermal resistance
- Hermetic sealed box for electric connections
- Forced air cooling
- Digital temp. control with auxiliary contacts
- Protection box for indoor installations.

Transformer testing

All routine tests are performed and special tests required by IEC 60076 can be performed in a modern and efficient test room.

Approval tests

Approval tests are automatically carried out on each transformer in order to check the compliance with the guaranteed data. These tests can be realised in front of the customer at extra-charges. A test report is delivered for each transformer.

The tests consist in particular:

- Measurement of the winding resistance.
- Measurement of the transformation ratio, the connections and polarity check.
- Measurement of the short circuit voltage (main taps) and of the load losses when returning to the reference temperature.
- Measurement of the losses and no load current.
- Industrial frequency test.
- Insulation test with induced voltage.
- Insulation test on off load commutators and auxiliary circuits, according to IEC 14-4 § 8.8

Type tests and special tests

Type and special tests may be carried out on request and in accordance with the agreement taken between the company and the customer. These tests will be carried out on one sample and charged in line with the agreed conditions during the order negotiation.

Type tests:

- Heating test
- BIL test 1,2/50 μ sec test

Special tests

- Insulation tests (IEC 14-4 part III)
- Measurement of the homopolaire impedance on three-phase transformers
- Dynamic resistance test during a short circuit
- Measurement of the noise level
- Measurement of the loadless current harmonics
- Measurement of absorbed power by the fan motors

All these tests, with the exception of the short circuit test, can be performed in house. Short circuit test shall be performed upon request in official and accredited laboratories.

A product guaranteed by

QUALITY MANAGEMENT

Manufacturing and Quality Assurance rules

The transformers are manufactured in accordance with the national and international standards and laws in force.

Transformers are complying with the IEC standards

We are specialized in adapting the product to the European standards.

The Quality Assurance of our product maintenance, installation and manufacturing is ensured and certified in line with the ISO 9001 standards.
